ABSTRACT
In this paper a direct method using parameterization technique is applied for solving some problems in calculus of variations. The parameterization technique based on Laguerre and Hermite polynomials is introduced to reduce a variational problem to quadratic programming problem. Examples are given to demonstrate the validity of method.

Keywords: calculus of variation, orthogonal polynomials, parameterization Technique.

INTRODUCTION
The calculus of variations is a branch of mathematical analysis that studies extrema and critical points of functionals (or energies). Functional minimization problems known as variational problems appear in engineering and science where minimization of functionals, such as Lagrangian, strain, potential, total energy, give the laws governing the systems behavior [1].

Some popular methods for solving variational problems are direct methods. A fast numerical method for solving calculus of variation problems was given by [1], the direct method of Ritz, Walsh functions [2], Laguerre series [3], shifted Legendre polynomial series [4], shifted Chebychev series [5], Fourier series [6] and nonclassical parameterization [7] have been applied to solve variational problems.

In this work, we propose a direct method using parameterization technique with Laguerre and Hermite polynomials for finding the extremal of some variational problems. The application of the method will convert the variational problem to quadratic
programming problem, then using Lagrange multiplier technique to find the unknown parameters.

**Orthogonal Polynomials**

Special orthogonal polynomials began appearing in mathematics before the significance of such a concept became clear. For instance, Laplace used Hermite polynomials in his studies in probability while Legendre and Laplace utilized Legendre polynomials in celestial mechanics. Some properties of Hermite and Laguerre are given because these are the most extensively studied and here the longest history [8].

**Hermite Polynomials and Their Properties**

Hermite polynomials and its applications have been studied for long and still attract attention. One can refer a long list of books and journals for advanced knowledge of Hermite polynomials and its extension, for example [9], for books, and [10],[11]and[12] for journals.

**Definition** [13]

The nth Hermite polynomials denoted by \( H_n(t) \) are given by

\[
H_n(t) = (-1)^n e^{-t^2} \frac{d^n}{dt^n} e^{t^2} \quad n = 0,1,2
\]

also \( H_n(t) \) can be expressed as

\[
H_n(t) = \sum_{k=0}^{[n/2]} (-1)^k \frac{n!}{k!(n-2k)!} (2t)^{n-2k} \quad \text{and } \left[ \frac{n}{2} \right] \text{ denotes the largest integer } \leq \frac{n}{2}
\]

The Hermite polynomials have many important properties are

- **The initial values**
  \[
  H_{2n}(0) = (-1)^n \frac{2n!}{n!}, \quad \dot{H}_{2n}(0) = 0
  \]
  \[
  H_{2n+1}(0) = 0, \quad \dot{H}_{2n+1}(0) = (-1)^n \frac{(2n+2)!}{(n+1)!}
  \]

- **Product property**
  \[
  H_n(t)H_m(t) = \sum_{k=0}^{\min(n,m)} \binom{n}{k} \binom{m}{k} H_{2k+n+m}(t) 2^k k!
  \]
  \[
  H_n(t)H_m(t) = n!m! \sum_{k=0}^{\min(n,m)} \frac{2^k H_{2k+n+m}(t)}{k!(n-k)!(m-k)!}
  \]

- **Integration property**
\[ \int_0^x H_n(t) dt = \frac{1}{2(n+1)}(H_{n+1}(x) - H_{n+1}(0)) \]

- Differentiation property
\[ \frac{dH_n(t)}{dt} = 2nH_{n-1}(t) \]
\[ \frac{d^2H_n(t)}{dt^2} = 4n(n-1)H_{n-2}(t) \]

- Operational matrix of derivative \( D_H \):
\[
\begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
2 & 0 & 0 & 0 & 0 & 0 \\
0 & 4 & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & 2n & 0
\end{pmatrix}
\]

Laguerre Polynomials and Their Properties

The Laguerre polynomials were introduced by Edmond Laguerre more than 150 years ago. Many applications of them on various problems in mathematics, physics and electrotechnics were found. The Laguerre polynomials are orthogonal polynomials with respect to the weighting function \( e^{-t} \) on the half-line \([0, \infty)\) they are denoted by the letter "L" with the order as subscript and normalized by the condition that the coefficient of the highest order term of \( L_n \) is \((-1)^n / n! \), [14].

Definition [15]
The \( n \)th Laguerre polynomials are given by the formula
\[ L_n(t) = e^t \frac{d^n}{dt^n} (t^n e^{-t}) \]
also \( L_n(t) \) can be expressed as
\[
L_n(t) = \sum_{k=0}^{n} \frac{(-1)^k (n^2)^k (n-k)!}{(k!)^2 (n-k)!} (t)^k
\]
The Laguerre polynomials have many important properties, are

- The initial values
\[ L_n(0) = n! \]
\[ \hat{L}_n(0) = -n \times n! \]

- Integration property

\[ \int_0^x L_n(t) \, dt = L_n - \frac{L_{n+1}(x)}{n+1} \]

- Differentiation property

\[ \hat{L}_n(t) = -n! \sum_{i=0}^{n-1} \frac{L_i(t)}{i!} \quad n \geq 1 \]

\[ L_n^m(t) = (-1)^m \frac{n!}{(m-1)!} \sum_{i=0}^{n-m} \frac{(n-(i+1))!}{i!(n-m-i)!} L_i(t) \]

- Operational matrix of derivative \( D_L \):

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 & 0 \\
2 & -2 & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
-n! & -n! & \cdots & \cdots & -n! & 0 \\
\end{bmatrix}
\]

Lagrange Methods and Quadratic Programming

Lagrange methods [16]

The Lagrange methods for dealing with constrained optimization problem are based on solving the Lagrange first-order necessary conditions. In particular, for solving the problem with equality constraints only:

Minimize \( f(x) \)

\[ g_j = 0 \quad j = 1, 2, \ldots, m < n \]

the Lagrangian function is follows:

\[ L(x, \lambda) = f(x) + \sum_{j=1}^{m} \lambda_j g_j(x) \]

\[ = f(x) + \lambda^T g(x) \]

\[ \lambda^T = (\lambda_1, \lambda_2, \ldots, \lambda_m) \] and \( g(x) = \begin{bmatrix} g_1(x) \\ g_2(x) \\ \vdots \\ g_m(x) \end{bmatrix} \)

where \( \lambda \) is an \((m \times 1)\) vector of Lagrange multipliers.
In general, we can set the partial derivative to zero to find the minimum:

\[
\frac{\partial L}{\partial x_i}(x, \lambda) = 0 \quad \text{for } i = 1, \ldots, n
\]

\[
\frac{\partial L}{\partial \lambda_j}(x, \lambda) = 0 \quad \text{for } j = 1, \ldots, m
\]

where \( x^* \) is the minimum solution and \( \lambda^* \) is the set of the associated Lagrange multipliers.

**Quadratic programming [16]**

An important special case is when the target function \( f \) is quadratic and the constraints are linear:

Minimize \( \frac{1}{2}x^TQx + x^Tc \)

subject \( Ax = b \)

Q is asymmetric matrix, \( x^T \) is transpose of \( x \) and the Lagrange necessary conditions become:

\[
L(x, \lambda) = \frac{1}{2}x^TQx + x^Tc + \lambda^T(Ax - b)
\]

\[
\frac{\partial L}{\partial x} = Qx + c + \lambda^TA
\]

\[
\frac{\partial L}{\partial \lambda} = Ax - b
\]

Since \( (\lambda^TA = A^T\lambda) \) therefore

\[
Qx + c + A^T\lambda = 0
\]

\[
Ax - b = 0
\]

If Q is nonsingular then the solution becomes:

\[
x = -Q^{-1}c + Q^{-1}A^T(AQ^{-1}A^T)^{-1}[AQ^{-1}c + b]
\]

\[
\lambda = -(AQ^{-1}A^T)^{-1}[AQ^{-1}c + b]
\]

**Direct Method Using Hermite Polynomials**

The simplest form of a variational problem can be considered as finding the extremum of the value of the functional [7]:

\[
J[x(t)] = \int_{t_0}^{t_1} F[x(t), \dot{x}(t), t]dt \quad \text{...(1)}
\]

To find the extreme value of \( J \), the boundary points of the admissible curves are known in the following form

\[
x(t_0) = \alpha, \quad x(t_1) = \beta \quad \text{...(2)}
\]
Suppose the variable $x_i(t)$ can be expressed approximately as

$$x_i(t) = \sum_{j=0}^{N_i} a_{ij} H_j(t) = a_i^T H(t) \quad i=1,2,...,n, \quad j=0,1,...,N \quad \cdots (3)$$

where $a_i = [a_{i0}, a_{i1}, ..., a_{iN}]^T$, $i=1,2,...,n$ are $(N+1) \times 1$ vector of unknown parameters with property that $a_{ij} = x_i(t_j)$ and $H(t) = [H_0, H_1, ..., H_N]^T$ is $(N+1) \times 1$ vector of Hermite polynomial $H(t)$.

Differentiate eq.(3), yields:

$$\dot{x}_i(t) = a_i^T \dot{H}(t) = a_i^T D_H H(t) \quad i=1,2,...,n \quad \cdots (4)$$

Where $D_H$ is the operational matrix of derivative for Hermite polynomials.

Substituting eqs.(3) and (4) into eq.(1), the functional $J$ becomes a nonlinear mathematical programming problem of unknown parameters $a_{ij}$, where $i=1,2,...,n$, and $j=0,1,...,N$. Hence to find the extremum of $J$, we solve

$$J(x) = \frac{1}{2} a^T H_a + c^T a \quad \cdots (5)$$

where $H = \int_{t_0}^{t_1} [H(t), D_H H(t)] dt$

$c = \int_{t_0}^{t_1} [t, H(t), D_H H(t)] dt$

eq.(3) and the boundary conditions in eq.(2) imply

$x(t_0) = a^T H(t_0) = \alpha, \quad x(t_1) = a^T H(t_1) = \beta \quad \cdots (6)$

The quadratic programming problem in eqs.(5) and (6) can be rewritten as follows:

minimize $J(x) = \frac{1}{2} a^T H_a + c^T a$

Subject to

$Fa - b = 0$,

where

$$F = \begin{pmatrix} H^T(t_0) \\ H^T(t_1) \end{pmatrix}, \quad b = \begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

The optimal values of unknown parameters, $a^*$, can be obtained easily using Lagrange multiplier technique as

$$a^* = -H^{-1} c + H^{-1} F^T (F H^{-1} F^T)^{-1} (F H^{-1} c + b)$$

Then substituting $a^* \text{ in eq}(3)$ to get the solution, we establish the detailed procedure via some problems.

The same procedure can be used with Laguerre polynomials and its operational matrix of derivative.
Numerical Examples

First order functional extremal with two fixed boundary conditions
Consider the problem of finding the minimum of the time-varying functional
\[ J(x) = \int_0^1 [x^2 + 2tx + \dot{x}^2] \, dt \] …(7)
with boundary conditions \( x(0)=2, \ x(1)=e^1+1 \), the exact solution is \( e^t + 1 \)
for solving this problem by the Hermite polynomials, let
\[ x(t) = a^T H = a_0 H_0 + a_1 H_1 + a_2 H_2 + a_3 H_3 + a_4 H_4 \] …(8)
Differentiate eq.(8) to get
\[ \dot{x}(t) = a^T D_h H(t) \] …(9)
where
\[
D_h = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 \\
2 & 0 & 0 & 0 & 0 \\
0 & 4 & 0 & 0 & 0 \\
0 & 0 & 6 & 0 & 0 \\
0 & 0 & 0 & 8 & 0
\end{pmatrix}
\]
Also, in view of boundary conditions, we have
\[ x(0) = a_0 - 2a_2 + 12a_4 = 2 \] … (10)
\[ x(1) = a_0 + 2a_1 + 2a_2 - 4a_3 - 20a_4 = e^1 + 1 \] …(11)
Now, by using eqs.(8) and (9), the cost function \( J \) may be rewritten as
\[ J(x) = \frac{1}{2} \int_0^1 [a^T H(t) H^T(t) a + 2a^T t D_h H(t) + a^T D_h H(t)(D_h H)^T(t) a] \, dt \] …(12)
Eqs(10-12) can be simplified to quadratic programming problem
minimize \( J(x) = \frac{1}{2} a^T H a + c^T a \)
Subject to \( Fa - b = 0 \),
where
\[ F = \begin{pmatrix}
H^T(0) \\
H^T(1)
\end{pmatrix} = \begin{pmatrix}
1 & 0 & -2 & 0 & 12 \\
1 & 2 & 2 & -4 & -20
\end{pmatrix}, \quad b = \begin{pmatrix}
2 \\
e^1 + 1
\end{pmatrix}
\]
\[ c^T = 2 \int_0^1 t(D_h H)^T(t) \, dt = \begin{pmatrix}
0 & 2 & 16 & 0 & -192 \\
3 & 0 & -5
\end{pmatrix}
\]
The optimal values of unknown parameters $a_i$, $i = 0,1,2,3,4$ can be obtained easily using Lagrange multiplier technique as

$$a_0 = 2.3068223$$
$$a_1 = 0.60484444$$
$$a_2 = 0.17953216$$
$$a_3 = 0.01755142$$
$$a_4 = 0.00435349$$

The approximate solution is: $x(t) = 2.3068223H_0 + 0.60484444H_1 + 0.179532168H_2 + 0.01755142H_3 + 0.00435349H_4$

Table (1) shows the approximate solution obtained by using Hermite polynomials with $M=4$ and the exact solution.

This problem also solved by using Laguerre polynomial to find approximate solution with \( M=4 \), the same result are obtained.

**First order functional extremal with a fixed and a moving boundary conditions**

We consider the same functional extremal of eq.(7) but with unspecified \( x(1) \), namely

\( x(0) = 2 \), \( x(1) = \text{unspecified} \)

Another condition may be found from \( F[t, x(t), \dot{x}(t)] \)

\( F_{x} \big|_{t=t_{0}} = 0 \), that is \( 2x + 2t \) at \( t = 1 \) or \( x(1) = -1 \)

In this case, the exact solution is \( x(t) = c_{1}e^{t} + c_{2}e^{-t} + 1 \), where

\[
c_{1} = \frac{e^{-2} - 1}{e^{t} + e^{-t}}, \quad c_{2} = \frac{1 + e^{t}}{e^{t} + e^{-t}}
\]

The equation (7) become \( J(x) = \int_{0}^{1} x^{2} + 2tx + \dot{x}^2 \)dt with boundary condition \( x(0) = 2 \), \( \dot{x}(1) = -1 \), for solving this problem by Laguerre polynomials, let

\( x(t) = a^{T}L = a_{0}L_{0} + a_{1}L_{1} + a_{2}L_{2} + a_{3}L_{3} + a_{4}L_{4} \) …(13)

Differentiate eq.(13) to get

\[
\dot{x}(t) = a^{T}D_{L}(t) \quad \ldots(14)
\]

where

\[
D_{L} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 & 0 \\
-2 & -2 & 0 & 0 & 0 \\
-6 & -6 & -3 & 0 & 0 \\
-24 & -24 & -12 & -4 & 0
\end{bmatrix}
\]

Also, in view of boundary conditions, we have

\( x(0) = a_{0} - 2a_{2} + 6a_{3} + 24a_{4} = 2 \) \ldots(15)

\( \dot{x}(1) = -a_{1} - 2a_{2} - 3a_{3} + 4a_{4} = -1 \) \ldots(16)

Now, by using eqs.(13) and (14), the cost function \( J \) may be rewritten as

\[
J(x) = \int_{0}^{1} [a^{T}L(t)L^{T}(t)a + 2a^{T}tD_{L}(t) + a^{T}D_{L}(t)(D_{L}(t)L)^{T}(t)a]dt \quad \ldots(17)
\]

Eqs(15-17) can be simplified to quadratic programming problem

\[
\text{minimize} \quad J(x) = \frac{1}{2} a^{T}Ha + e^{T}a
\]

subject to

\( Fa - b = 0 \),

Solution of Problems in Calculus of Variations Using Parameterization Technique

where

\[
F = \begin{pmatrix} L^T(0) \\ D_1 L^T(1) \end{pmatrix} = \begin{pmatrix} 1 & 0 & -2 & 6 & 24 \\ 0 & -1 & -2 & -3 & 4 \end{pmatrix}, \quad b = \begin{pmatrix} 2 \\ -1 \end{pmatrix}
\]

\[
c^T = 2 \int_0^1 t(D_1 L)^T(t) \, dt = \begin{pmatrix} 0 & -1 & -8/3 & -15/2 & -112/5 \end{pmatrix}
\]

\[
H = 2 \int_0^1 [L(t)L^T(t) + D_1 L(t)(D_1 L)^T(t)] \, dt
\]

The approximate solution is:

\[
x(t) = a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4
\]

The optimal values of unknown parameters \(a_i, i = 0, 1, 2, 3, 4\) can be obtained easily using Lagrange multiplier technique as

\[
a_0 = 0.66805726 \\
a_1 = 1.79719137 \\
a_2 = -0.3210646 \\
a_3 = -0.0313954 \\
a_4 = 0.01521889
\]

The approximate solution is:

\[
x(t) = 0.66805726L_0 + 1.79719137L_1 - 0.3210646L_2 - 0.0313954L_3 + 0.01521889L_4
\]

This problem also solved by using Hermite polynomial to fined approximate solution with M=4, the same result are obtained.

Conclusion

Direct parameterization technique was employed for finding the solution of first order functional extremal with fixed and moving boundary conditions using Laguerre and Hermite polynomials as abases functions.

The presented methods with Laguerre and Hermite basis functions were applied to solve variational problems and the same results were obtained.
