CFD investigation of the erosion severity in 3D flow elbow during crude Oil contaminated sand transportation

Abstract- During upstream petroleum production operations, crude oil and sand eroded from formation zones are often transported as a mixture through pipes up to the well heads and between well heads and flow stations. The sand particles are carried by the flow momentum in streamlines that impinge the pipe walls, in particular at the elbows, resulting in seriously erosive damages. This can lead to a disastrous and costly failure in the system. Therefore, computing of erosion rate during the system operation is indispensable for predicting any potential failure in advance, and hence avoid it. Among all the fittings employed in piping systems, elbows are the most likely subjected to erosion resulting from sand particles carried with oil, where those particles deviate from the mainstream and impact the walls while passing through the bended section of elbows. To reduce the erosive damage produced by the solid particles, a numerical simulation based erosion prediction model has been employed to compute the relative erosion severity. In this study, the potentials required to simulate the current problem comprehensively, various physical aspects have been combined together including flow turbulence, particle tracking, and erosion simulation. In addition to the comprehensive insights offered by the computational simulation of crude oil flow, high costs along with tedious efforts required for traditional experimentations can be avoided. The current analysis offers priceless physical insight towards serve this model as an alternative sand management tool, and can be used to quantify oil recovery. Furthermore, it can identify limiting steps and components; form a computer-aided tool for designing and optimizing the future pipe systems in order to enhance their lifetime through improving their erosion resistance, which is definitely will save considerable amount of time and cost.

Keywords- Crude oil, Sand; Contamination; CFD; Erosion; Solid particle; Elbow.

1. Introduction

One of the main ways, through which crude oil is damaging the environment nowadays, is its leakage from natural deposits [1]. During upstream petroleum production practices, sands from reservoirs are often transported up to the well heads and from the well heads to flow stations. The entrained sand may deposit on the walls of the elbow pipe due to pressure drop causing problems of erosive wear in the pipe elbow and then crude oil Leakage (Figure 1). The sand particles are carried by the flow momentum in streamlines that impinge the pipe walls, in particular at the elbows, resulting in seriously erosive damages. This can lead to a disastrous and costly failure in the system [2]. Pipe elbows erosion caused by sand particles has been of great interest recently due to its crucial role in the oil industry as well as practical applications concerning materials erosion. Both sciences of fluid dynamics and materials engineering are required together for addressing the problems involving erosion caused by solid particles carried with the fluid flow [3-5]. Therefore, predicting any potential failure in advance, and hence avoid it by computing the erosion rate during the system operation is indispensable.

The lack of efficient testing tools to evaluate the erosion rate resulting from flow through piping systems has been hampering the development of anti-erosion elbows. The phenomenon of sand erosion is too complicated as it incorporates a wide range of hydrodynamic and structural factors contributing either positively or negatively in its severity including oil characteristics and its flow rate, the sand rate and its particles shape. This is why it has become of great interest to reduce the damaging effects of the erosion resulting from solid particles through manipulating these design factors simultaneously.
Figure 1: Piping systems in oil industry showing erosion occurs in elbows.

Therefore, various predicting methods were developed to limit the erosion consequences. Amongst them, the CFD based erosion simulation has been found quite efficient and applicable to the too complicated engineering applications [6, 7].

In this study, a three-dimensional CFD model has been developed that describes a turbulent transport of sand particles and crude oil through elbows to predict the erosions rates, where various physical aspects have been combined together including flow turbulence, particle tracking, and erosion simulation.

2. CFD modeling
I. Computational domain

As the numerical modelling of an entire elbow requires costly and powerful computing resources, not to mention the excessively long-time simulation needed; the investigated domain in the current simulation is focused on the three-dimensional section of the elbow only (Figure 2).

II. Modeling Equations

1. The Turbulence Flow Model

A Newtonian and incompressible fluid having constant density is considered herein. The RANS forms of the momentum conservation as well as continuity equations are formulated as [8];

\[ \rho \frac{\partial \mathbf{u}}{\partial t} + \rho \mathbf{u} \cdot \nabla \mathbf{u} + \nabla \cdot (\rho \mathbf{u} \mathbf{u}) = -\nabla p + \nabla \cdot (\mu (\nabla \mathbf{u} + (\nabla \mathbf{u})^T) + F \quad \ldots \quad (1) \]

\[ \rho \nabla \cdot \mathbf{u} = 0 \quad \ldots \quad (2) \]

Where \( \mathbf{U} \) represents the mean velocity, while \( \otimes \) stands for the outer vector product.

In this work, the \( k-\omega \) model is carefully chosen over the \( k-\varepsilon \) model because it is more accurate than the \( k-\varepsilon \) model for flows involving strong streamline curvature [8], where formulation of this turbulence model is as follows:

\[ \rho \frac{\partial k}{\partial t} + \rho \mathbf{u} \cdot \nabla k = \left( P_k - \rho \beta^* k \omega + \nabla \cdot \left( \mu + \sigma^* \mu_T \right) \nabla k \right) \quad \ldots \quad (3) \]

\[ \rho \frac{\partial \omega}{\partial t} + \rho \mathbf{u} \cdot \nabla \omega = \left( \alpha \frac{\omega}{k} P_k - \rho \beta^* \omega^2 + \nabla \cdot \left( \mu + \sigma \mu_T \nabla \omega \right) \right) \quad \ldots \quad (4) \]

Where,

\[ \mu_T = \rho \frac{k}{\omega} \quad \alpha = \frac{13}{25} \quad \beta = \beta_0 f_\beta \quad \beta^* = \beta_0^* f_\beta \quad \ldots \quad (5) \]

\[ \sigma = \frac{1}{2} \quad \sigma^* = \frac{1}{2} \quad \ldots \quad (6) \]

\[ \beta_0 = \frac{13}{25} \quad f_\beta = \frac{1 + 70X_k}{1 + 80X_k} \quad X_k = \frac{|\Omega_{ij} \Omega_{jk} S_{ki}|}{(\beta_0 \omega)^2} \quad \ldots \quad (7) \]

\[ \beta_0^* = \frac{9}{100} f_\beta^* = \frac{1}{1 + 80X_k^2} \quad X_k \leq 0 \]

\[ X_k > 0 \quad \ldots \quad (8) \]

Where \( \omega_{ij} \) represents the mean tensor of rotation rate.

\[ \Omega_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \right) \quad \ldots \quad (9) \]

And \( S_{ij} \) is the mean strain rate tensor.

\[ S_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i} \right) \quad \ldots \quad (10) \]
2. Particle Motion in a Fluid Model

According to Newton’s second law, the particle momentum can be formulated as [8];

\[
P_k = \mu_T \left( \nabla u : (\nabla u + (\nabla u)^T) - \frac{2}{3} \nabla u \cdot u \right) \rho_k \nabla \cdot u \quad \ldots (11)
\]

Where \( m_p \) refers to the particle mass in kg, \( v \) is the particle velocity in m/s, \( F_D \) stands for the drag force in N, \( F_g \) is the vector of gravitational force in N, and \( F_{ext} \) represents any other external source in N.

The drag force \( (F_D) \) can be computed as;

\[
F_D = \left( \frac{1}{\tau_p} \right) m_p (u - v) \quad \ldots (12)
\]

Where \( \tau_p \) is the response time of particle velocity in sec, \( u \) stands for the flow velocity in m/s. The instantaneous flow velocity presented in the drag force of the turbulent dispersion term is rewritten as;

\[
u = U + u' \quad \ldots (14)
\]

Where \( U \) is the time mean velocity while \( u' \) is a turbulent fluctuation velocity, which is defined as;

\[
u' = \varphi \sqrt{\frac{2k}{3}} \quad \ldots (15)
\]

Where \( k \) is the turbulent kinetic energy, while \( \varphi \) is a normally distributed random number with zero mean and unit standard deviation. The gravitational force is formulated as;

\[
F_g = m_p g \left( \frac{\rho_p - \rho}{\rho_p} \right) \quad \ldots (16)
\]

Where \( \rho_p \) represents the particle density in kg/m\(^3\), \( \rho \) stands for the surrounding fluid density in kg/m\(^3\), while \( g \) is the gravitational direction.

3. Erosion Models

The Erosion feature calculates the rate of erosive wear or the total mass removed per unit area due to the impact of particles at a boundary. The following three models have been modeled [4-7].

A. The Finite Model

Finnie defined the volume removed from a surface as:

\[
V = \frac{c M U^2}{4p(1+\frac{m r^2}{1})} \left[ (\cos \alpha)^2 \right] \quad \tan \alpha > \frac{p}{2}
\]

\[
V = \frac{c M U^2}{4p(1+\frac{m r^2}{1})} \left[ (\sin 2\alpha)^2 - 2(\sin \alpha)^2 \right] \quad \tan \alpha \leq \frac{p}{2}
\]

Where the parameters are defined as follows:

- \( c \) (dimensionless) is the fraction of particles cutting in an idealized manner.
- \( M \) [kg] is the total mass of eroding particles.
- \( U \) [m/s] is the magnitude of the incident particle velocity.
- \( p \) [Pa] is the material Vickers hardness.
- \( m \) [kg] is the mass of an individual particle hitting the surface.
- \( r \) [m] is the average particle radius.
- \( I \) [kg-m\(^2\)] is the moment of inertia of an individual particle about its center of mass. For an isotropic sphere, \( I=2mr^2/5 \).
- \( \alpha \) [rad] is the angle of incidence, with \( \alpha=0 \) tangent to the surface and \( \alpha=\pi/2 \) normal to the surface.
- \( P \) is a dimensionless parameter, defined as \( P=K/(1+mr^2/I) \), where \( K \) (dimensionless) is the ratio of vertical and horizontal forces acting on the particle.

In the Finnie model, particles are assumed to remove mass from the surface via an idealized cutting mechanism. It does not predict any erosive wear by particles at normal incidence to a surface, and is recommended for modeling erosion of ductile materials by particles at small angles of incidence.

B. The Erosion Rate (E/CRC) Model

The E/CRC model defines the erosion rate in terms of the ratio of mass lost by the surface to mass of incident particles:

\[
E = CF_s (BH)^{-0.59} \left( \frac{v}{1[\text{m/s}]} \right)^n F(\alpha) \quad \ldots (19)
\]

\[
F(\alpha) = \left( \frac{5.40\alpha - 10.11\alpha^2 + 10.93\alpha^3 - 6.33\alpha^4 + 1.42\alpha^5}{6} \right) \quad \ldots (20)
\]

Where \( C \) is a dimensionless model coefficient, \( F_s \) is the particle shape coefficient (dimensionless), and \( BH \) is the Brinell hardness of the wall material (dimensionless). The angle of incidence \( \alpha \) is measured in radians.

C. The Erosion rate (DNV) Model

The DNV model defines the erosion rate in terms of the ratio of mass lost by the surface to mass of incident particles:

\[
E = K \left( \frac{v}{1[\text{m/s}]} \right)^n F(\alpha) \quad \ldots (21)
\]
Where \( K \) and \( n \) are constants that depend on the surface material.

III. The grid used

The finite-volume method was used to discretize the governing equations, which are in turn solved using a commercial CFD code having the power to address multi-physics problems (COMSOL v5.2). Grid sensitivity has been performed to ensure that the solutions acquired using the selected mesh is independent of the grid size. The selected grid consists of 44772 domain elements in total, 8908 boundary elements, and 590 edge elements, which was found to provide sufficient spatial resolution (Figure 3). An iterative solution for the coupled equations was followed, where an error criterion of \( 1.0 \times 10^{-6} \) was considered sufficient enough to achieve the solution convergence. The solution was considered to be convergent when the relative error was less than in each field between two consecutive iterations.

The initial and boundary conditions, the erosion prediction procedure in this work is a comprehensive procedure that based on a three-dimensional CFD technique, which has three major steps: flow modeling, particle tracking, and erosion prediction. The flow initial and boundary conditions have been listed in Table 1 [9].

3. Results

Figure 4 shows the velocity distribution of the crude oil passing in the pipe elbow. The figure shows there is a separation zone after the bend which is consistent with the results of Homicz [10]. Figure 5 shows a corresponding pressure distribution in the pipe elbow. The visualizations of the sand particle trajectories transport through the pipe elbow are shown in Figure 6. Particles that move through the pipe bend without touching the walls have been hided; therefore the only particles that have made contact with surfaces of the pipe bend are shown. The color expression is the acute angle of incidence in degrees, measured from the surface normal. It is clear that the particles only strike the surface at grazing angles.

Three different erosion models are used to simulate the rate of erosive wear on the surface of the pipe elbow of the contaminated crude oil with sand particles. Figures 7-9 show the Finnie, DNV, and E/CRC erosion respectively. An example of erosion happens in pipe elbow during flow a contaminated crude oil with sand particles shows in Figure 10 with good similarity to the CFD model.
Figure 5: Pressure [Pa] in the pipe elbow.

Figure 7: Rate of erosive wear [kg/m².s] on the pipe walls, modeled using the Finnie model.

Figure 8: Rate of erosive wear [kg/m².s] on the pipe walls, modeled using the DNV model.

Figure 9: Rate of erosive wear [kg/m².s] on the pipe walls, modeled using the ECRC model.

Figure 10: Visual comparison between examples of the real erosions occurs in elbows and the result of the CFD model.
4. Conclusion

1. Three-dimensional CFD model has been developed that describes a turbulent transport of sand particles and oil through elbows to simulate the erosions.

2. The comprehensive simulation model consists of turbulent modeling, particle tracking, and erosion simulation.

3. It was found that the model presented has the potentials to provide better understanding for the, complexly interacting and transporting phenomena, which are quite hard to be investigated experimentally.
