#### Abstract

In the NC roughing phase of cavities, process planar needs to find the machining layers as well as the feasible cutters for these layers. This Paper deals with the issues of Cavity Construction based on Surface of revolution technique using cubic Bezier curve as a generator curve. First the generator curve is constructed in $x-z$ plane then allowing it to revolve through $\mathbf{3 6 0}^{\circ}$ about z-axis in order to generate the required surface cavity. A strategy of Maximum (critical cutter size) and Machining layers determination is also introduced in this paper. Numerical iteration is used for this purpose using MATLAB programming system to reduce the computational time. A comparison is made between different machining cavities critical cutter size and using cutters smaller than the critical size showing a wide reduction in the length of circular tool path(s) (CL) and the volume of removed metal (VRM).Numerical examples are presented to illustrate the proposed system.

Keywords: NC Roughing, VRM, CL, Cutter Selection, Inverse Point Interpolation.

## 1.Introduction

It has been proven to be very difficult for manufacturing engineers to select cutters and determine machining layers [1-4]. The primary objective in NC machining is the efficiency of mainly two machining
stages namely roughing and finishing machining, since the reduction in roughing and finishing time can considerably increase productivity, which, in turn, leads to lower manufacturing cost [5,6]. Roughing is

Eng. \& Technology, Vol.25, No.1, 2007
to remove redundant material from a primary row stock, while finishing is to remove residual material along the surface after roughing is applied.

A surface of revolution is a three- dimension surface entity generated by the revolution of plane curve (generator curve), about an axis of revolution through a given angle [7]. The surfaces generated by this approach are symmetrical about the axis of rotation and have different industrial applications such as some of plastic extrusion blow molds, injection blow molds, symmetrical extrusion and deep drawing dies [8] (see Fig.1). In this research the Bezier curve is taken as the generator curve for defining the surface cavity. Since the curvature of surfaces generated by revolution of Bezier curve is highly variant, the surface of each boundary contour differs in shape from one to another along the depth of the cavity. Therefore, care must be taken in setting the depth of cut (see Fig.2). The cutter diameter must also be selected with care, as the gouging between the cutter and part surface needs to be controlled (see Fig.3). Increasing both cutter diameter and depth of cut will increase the roughing process efficiency $[9,10]$.

Gouging is particularly pernicious problem in free form surface machining, and it is often encountered when the tool size is too large relative to the concave radius of curvature. Accordingly, both cutter selection and machining layers determination must be accurately selected in NC machining of freeform cavities. While the principle is simple, the practice is significantly more complex and number of common pitfalls can be identified.

NC Roughing Machining of Cavities Defined by Surface of Revolution Approach

## 2.Related Work

There are variety of methods, which have been done in the area of cutter selection. Yen-Hung Chem et al. [1] proposed an approach to handle the cutter selection and machining plane determination together for roughing and finishing process in NC machining of complex cavity.

Some techniques were presented by Hamdan W. [9] to determine the optimal cutter selection for freeform Bezier surface based on the minimum radius of curvature of the surface for finishing and based on the smaller polygon of characteristic of Bezier polyhedron which consists of nine polygons.

The two-dimensional pocket machining bounded by polygons and their cutter size determination based on circle fitting method was presented by Bala and Chang [11]. Lee and chang. [12] determined the cutter size for three and five axis machining of sculptured surfaces based on the cutting shapes of the part.

Linn and Mishra [13] determined the optimal machining sequence on planar surfaces based on integer programming (IP) approach.

Sinclair B. et al. [14] organized a method for describing a three dimensional irregular object by sectioning the object with a finite number of parallel planes separated by very small distance, though the author assumed that the object should be without holes.

Person H. [15] described an algorithm for machining arbitrarily shaped pockets using NC milling machine and throughout shrinking the pocket boundary in stepwise fashion.

Eng. \& Technology, Vol.25, No.1, 2007

However, none of the above work has addressed the issues of machining cavities defined by surface of revolution and non of them determined the relation between cutter size and machining depth of layer.

This work is dedicated to the development of a surface of revolution algorithm for construction three-dimensional cavity and addresses the inverse point interpolation approach to determine the relation between maximum cutter size and machining layer depth.

## 3. Generation a Surface of

## Revolution

Generation a surface, which involves purely rotation of a plane curve (which is called generation curve) in $\mathrm{X}-\mathrm{Y}, \mathrm{X}-\mathrm{Z}$ or $\mathrm{Y}-\mathrm{Z}$ plane about any axis of rotation, then we call the resultant surface will be referred to as a surface of revolution [16]. The generator curve adopted in this paper is a cubic Bezier curve.

### 3.1 Generation Bezier Curve

Bezier curve is one of the famous tools in CAGD [16]. To generate a Bezier curve, first the designer needs to choose four control points, two ends points of the curve ( $\mathrm{P} 1, \mathrm{P} 2$ ) and two other points ( $\mathrm{P} 3, \mathrm{P} 4$ ) which determine the characteristic polygon of curve being generated. Therefore, the designer can control the curve shape in predictable way by changing only a few simple control points as shown in Fig. 4.

In matrix form the cubic Bezier curve can be written as follows [16] :
$\mathbf{P}(\mathrm{u})=\mathbf{U}$ MB $\mathbf{P}^{\mathrm{T}}$.
Where :
$\mathbf{U}$ is theindependent parameter matrix:

NC Roughing Machining of
Cavities Defined by Surface of Revolution Approach
$\mathbf{U}=[1 \mathrm{u} u 2 \mathrm{u} 3] \quad \mathrm{u} \in[0,1]$
MB is the cubic Bezier vector
$\mathrm{MB}=\left[\begin{array}{rrrr}1 & 0 & 0 & 0 \\ -3 & 3 & 0 & 0 \\ 3 & -6 & 3 & 0 \\ 1 & 3 & -3 & 1\end{array}\right]$
$\mathbf{P}^{\mathrm{T}}$ is the control point vector
$\mathbf{P}^{\mathrm{T}}=\left[\begin{array}{l}\mathbf{P}_{1} \\ \mathbf{P}_{2} \\ \mathbf{P}_{3} \\ \mathbf{P}_{4}\end{array}\right]$

The surface of revolution is constructed by revolving the generated Bezier curve (generator curve) about Z-axis in X-Z plane, where the Z -axis is assumed to be the depth of the cavity. Therefore, the vector equation of the generator curve is given by, (as shown in Figure 5) :

$$
\mathbf{r}(\mathrm{u})=[\mathbf{P x}(\mathrm{u}) 0 \mathbf{P z}(\mathrm{u})] \ldots .(2)
$$

where $\mathrm{Px}(\mathrm{u})$ and $\mathrm{Pz}(\mathrm{u})$ are the position vector of a general point on the generator BEZIER curve in X-Z plane which is given in Fig.(4):

$$
\begin{aligned}
& \mathbf{P}(\mathrm{u})=(1-\mathrm{u})^{3} \mathbf{P}_{1}+3 \mathrm{u}(1-\mathrm{u})^{2} \mathbf{P}_{2} \\
& +3 \mathrm{u}^{2}(1-\mathrm{u}) \mathbf{P}_{3}+\mathrm{u}^{3} \mathbf{P}_{4} \ldots \ldots . .(3)
\end{aligned}
$$

Rewrite Equation (2) as a homogenous vector, we get :
$\mathbf{P}(\mathrm{u})=[\mathrm{Px}(\mathrm{u}) 0 \mathrm{Pz}(\mathrm{u}) 1] \ldots \ldots$. .(4)

For rotation the generator curve through angle $\theta$ about the Z -axis, equation (4) will be extended from a curve $\mathrm{P}(\mathrm{u})$ of one parameter ( u ) to a surface $S(u, \theta)$ of two parameters (u) and $(\theta)$ as follows:

Eng. \& Technology, Vol.25, No.1, 2007
$\mathbf{S}(\mathrm{u} \theta)=[\mathrm{Px}(\mathrm{u}) 0 \mathrm{Pz}(\mathrm{u}) 1]$. MR
where MR is the rotation matrix in clockwise direction about Z-axis, which is given by :
$M R=\left[\begin{array}{cccc}\operatorname{Cos} \theta & \operatorname{Sin} \theta & 0 & 0 \\ \operatorname{Sin} \theta & \operatorname{Cos} \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1\end{array}\right]$

Substituting MR in equation (5) yields :

S(u $\quad \theta)=[\mathbf{P x}(\mathrm{u}) \operatorname{Cos} \theta$
$\mathbf{P x}_{\mathrm{x}}(\mathrm{u}) \operatorname{Sin} \theta$ $\mathrm{Pz}(\mathrm{u})$ 1]
where $0 \leq \mathrm{u} \geq 1$
and $\quad 0 \leq \theta \geq 2 \pi$
Figure (6) depicts different surfaces obtained from applying Equation (7) to their generator curves.

## 4.Cutter Selection and Machining Layers Determination.

In this study the following useful constraints are suggested in order to facilitate the machining process:
1.The part surface of the raw material lies in the $x-y$ plane.
2.The tool axis is parallel to Z-axis, therefore it is perpendicular to the machining or part surface.
3.The machining layers are the intersection of series of planes perpendicular to the Z-axis .
4.A series of machining layers MLi are separated by a constant distance $\Delta Z$ between each adjacent layers in order to select a proper cutter size.
5.The machining layers are numbered from the top of the cavity to its

NC Roughing Machining of Cavities Defined by Surface of Revolution Approach

bottom sequentially, as indicated in Figure (7.a).
Since the surface of revolution approach is used to define the shape of the cavity, the contours of the intersection between machining layers and the surface cavity are always circular contours of different radii, but of the same centers (see Figure 7.b).
According to the constraint (4) above, below a simple rule for determining the maximum cutter size for each machining layer.First of all Zcoordinates of intersected points must be found $(\mathrm{Zi}, \mathrm{Zi}+1, \mathrm{Zi}+2, \mathrm{Zi}+3$, $\mathrm{Zi}+4, \ldots \ldots . . \mathrm{Zmin}$ ) (see Figure 8 ) as follows:
$\mathrm{Zi}=\mathrm{Zmax}-(\mathrm{i}-1) . \Delta \mathrm{Z}$
where $\mathrm{i}=1,2,3,4,5, \ldots \ldots \ldots, \mathrm{~N}$
where N is the number of machining layers which is given by :
$\mathrm{N}=\mathrm{INT}($ Zmax-Zmin)/ $\Delta \mathrm{Z} \ldots$...(9)
X -coordinates of intersected points (Xi , Xi+1, Xi+2, Xi+3, Xi+4, ......... Xmin ) can not be calculated by the same method, since that BEZIER curve is a freeform curve, therefore $\Delta \mathrm{X}$ is unknown, the values of the indepented variables (ui , ui+1, $u i+2$, ui +3 , ui $+4, \ldots \ldots$. umin ) are required to be found. To do that, the Inverse Point Interpolation technique may be a useful way to find these values by substituting a successive values of $(\mathrm{Zi}, \mathrm{Zi}+1, \mathrm{Zi}+2, \mathrm{Zi}+3, \mathrm{Zi}+4$, ......... Zmin ) in Equation (3) to obtain :
$\mathrm{Zi}=(1-\mathrm{ui}) 3 \mathrm{P} 1 \mathrm{z}+3$ ui (1-ui ) $2 \mathrm{P} 2 \mathrm{z}+$ 3ui 2 (1-ui ) P3z + ui 3 P 4 z .(10)

Eng. \& Technology, Vol.25, No.1, 2007

Using the Simple Iteration Method on Equation (10) over different calculated values of Zi , we shall find the values (ui , ui $+1, u i+2, u i+3$, ui $+4, \ldots \ldots .$. umin ) corresponding to $(\mathrm{Zi}, \mathrm{Zi}+1, \mathrm{Zi}+2, \mathrm{Zi}+3, \mathrm{Zi}+4, \ldots$ Zmin). Substituting these values in Equation (3) again, yields :
$\mathrm{Xi}=(1-\mathrm{ui})^{3} \mathrm{P} 1 \mathrm{x}+3$ ui $(1-\mathrm{ui})^{2} \mathrm{P} 2 \mathrm{x}+$ $3 u i^{2}$ (1-ui ) P3x $+u^{3} P 4 x$ (11)

Now refer to Fig.(8), the maximum cutter radius ( Ri max) of a given machining layer is the distance from Z-axis to the X - coordinate of the intersected points of that machining layer i.e.,

Ri max $=\mathrm{INT}(\mathrm{Xi})$
When the technologist use the maximum cutter radius, each layer requires one machining pass, since the maximum cutter radius is equal to the radius of the machining layer as shown in Fig.(9), the maximum Volume of Removed Metal (VRM) will be removed and minimum length of circular path (LC) will result, consequently, productivity increases as the machining time decreases in this case the length of circular path represent the circumferential of the cutter, where :
$\mathrm{VRMi}=2 \pi$ Ri max. $\Delta \mathrm{Zi}$...(13)
$\mathrm{LCi}=2 \pi$ Ri max $\qquad$
where:
VRMi : the Volume of Removed Metal of (i) layer .
The total (VRM) and (LC) of the cavity (all machining layers) is given by :

$$
\begin{aligned}
& i=N \\
& i=1 \\
& i=N \\
& i=1
\end{aligned}
$$

NC Roughing Machining of<br>Cavities Defined by Surface of Revolution Approach

$(\mathrm{VRM})_{\mathrm{T}}=\Sigma 2 \pi \operatorname{Rimax} . \Delta \mathrm{Zi} . . .(15)$
$(\mathrm{LC})_{\mathrm{T}}=\Sigma 2 \pi \mathrm{Ri} \max$
When the cutters of existing NC machine tool magazine are smaller than the maximum cutter size, the technologist is obliged to select these cutters, in this case each machining layer requires more than one machining pass as shown in Figure (9), consequently the machining time will increase since :
$\ddot{y}$ The (VRM) for each machining layer will be removed over a different number of passes.
$\ddot{y}$ The total length of circular tool path will increase.
Referring to Fig.(10), the (VRM) and (LC) of each pass can be calculated as follows:

VRM/pass $=\pi . \Delta \mathrm{Z}_{\mathrm{i}} \cdot \mathrm{C}_{\mathrm{i}} \cdot \zeta \ldots \ldots$. (17)
LC/pass $=\pi . \mathrm{C}_{\mathrm{i}} \cdot \mathrm{i}$
where:

Ci : the cutter diameter
$\zeta=1,2,4,6,8, \ldots \ldots \ldots ., 2(\xi-1)$
where:
$\xi$ : the number of passes which is given by :
$\xi=\left(\mathrm{R}_{\mathrm{e}} / \mathrm{C}_{\mathrm{i}}\right)+0.5$
$\mathrm{Re}=0.2 \mathrm{Ri}$
where Re is the effective diameter to avoid the interlacing between the circular paths.

## 5. Illustrative Examples and Comparison

Two experimental examples illustrate the feasibility of proposed strategy for practical use.

Eng. \& Technology, Vol.25, No.1, 2007

## Example I

The first example is shown in Fig.(11). Fig.(11.a), shows the generator Bezier curve. Revolving of this curve about Z -axis through an angle of rotation ranging from [0 to $2 \pi$ ], gives the surface of the intended cavity as shown in Fig.(11.b).

A series of ten machining layers MLi ( $\mathrm{i}=1, \ldots . ., 11$ ) are used to intersect the part design to find the maximum cutter size on each machining layer. The number of machining layers (NML) is calculated with a depth of cut $\Delta \mathrm{Z}=0.5$, where : NML=(( Zmax - Zmin )/ $\Delta \mathrm{Z}$ ) +1
$\qquad$
The intersection contours of the ten machining layers in X-Y plane and on3D space system are shown in Figs. (11.c) and (11.d) respectively.

The X-coordinates, maximum cutter size, length of circular path(s) and volume of removed metal for each machining layer are listed in Table (1).

Since the maximum cutter size for each machining layer is not always available, it is very convenient to show the effect of different cutter sizes on the volume of removed metal. Assuming that the NC machine tool magazine contains the following cutters, $\mathrm{T}=[\mathrm{T} 1 \mathrm{~T} 2 \mathrm{~T} 3 \mathrm{~T} 4 \mathrm{~T} 5$ ] having the diameters, $\mathrm{C}=\left[\begin{array}{lllll}2 & 5 & 8 & 10 & 12\end{array}\right]$ respectively.

Table (2) shows the feasible and unfeasible cutters for specified machining layer and the number of required passes for each machining layer corresponding to each cutter.

Table (3) shows the (VRM) per pass for feasible cutters, optimum cutters for each machining layer and the total (LC) for each feasible cutter at a given machining layer.

NC Roughing Machining of Cavities Defined by Surface of Revolution Approach

## Example II

Fig.(12.a) and illustrates the generated Bezier curve with its control points and corresponding revolved surface cavity respectively. In this example a series of fifteen machining layers with ( $\Delta \mathrm{Z}=0.6$ ) are used to intersect the part design in order to find the feasible cutter size for each machining layer.

The intersection contour of some machining layers on 2 and 3 dimensional space system are shown in Fig.(12.c) and (12.d) respectively. The X-coordinates, maximum cutter size and volume of removed metal of the sixteen machining layers are calculated and arranged in Table (4) below. In this example the suggested NC machine tool magazine contain the five cutters shown in Table (5) with their corresponding results to be feasible or unfeasible cutter. Table (6) shows the (VRM) per pass for feasible cutters, optimum cutters for each machining layer and the total (LC) for each feasible cutter at a given machining layer.

## 6.Concluding Remarks

In this paper, a strategy of generation cavities based on surface of revolution approach is presented. The generator curve is a cubic Bezier curve, therefore the user has the capability of estimating the shape of the generator curve due to the power of the control Bezier polygon for reflecting its shape. A methodology of critical cutter size and machining layers determination are also presented in this work using the simple iteration method as a powerful numerical analysis tool. Both strategies were coded in MATLAB,

Eng. \& Technology, Vol.25, No.1, 2007
result in a significant reduction in computation time.

In particular, the following results can be deduced confidently:

The volume of the removed metal is inversely proportional to the machining layers as shown in Fig.(13), since that cutters radii are decreased from the top of the cavity to its bottom. Therefore, Fig.(14) shows that the volume of removed metal is directly proportional to the cutter radii.

According to the results obtained from Tables 2, and 6 the relation between cutter diameter versus number of passes is plotted in Fig.(15), which exhibits that as the cutter diameter increases, a wide reduction in the number of passes is obviously noticed, due to the increase of surface area of the cutter.

Since the length of circular tool path (LC) is dependent on the cutter diameter and number of passes, (LC) is plotted in 3D space system as a function of two main variables as shown in Fig.(16) . From this Figure it is observed that as the cutter diameter increases, the number of passes decreases, but the length of circular tool path (LC) is increased since the centre of the cutter is far away from the centre of the cavity, resulting in a wide increase in the circumferential length of the tool path.
