Abstract

The set of all $n \times n$ non singular matrices over the field $F$ form a group under the operation of matrix multiplication. This group is called the general linear group of dimension $n$ over the field $F$, denoted by $\text{GL}(n,F)$. The subgroup from this group is called the special linear group denoted by $\text{SL}(n,F)$.

We take $n=2$ and $F=2^k$ where $k$ natural, $k>1$. Thus we have $\text{SL}(2,2^k)$. Our work in this thesis is to find the Artin's exponent from the cyclic subgroups of these groups and the character table of it's.

Then we have that: $a(\text{SL}(2,2^k))=2^{k-1}$.

Keywords: Linear Group, Special Group, Exponent.

1-Introduction

In this work our focus will lie on the representation and character theory of finite groups. $R(G)$ is the group of all rational valued characters of $G$ under point-wise addition, and $T(G)$ is the group generated by the induced characters from the principal characters of certain subgroups of $G$ satisfying the three conditions of Solomon theorem. Solomon theorem states that the factor group $R(G)/T(G)$ has a finite exponent dividing $|G|$. E-Artin in (1927) proved that every rationally valued character of $G$ is a rational sum of representation character of $G$, or in other words, the exponent of $R(G)/T(G)$ is finite.
In (1968) Lam proved a sharp form of Artin’s theorem, he determined that the least positive integer \( A(G) \) such that \( A(G) \Phi \) is an integral linear combination of the induced principal characters of cyclic subgroups, for any rational valued character \( \chi \) of \( G \), \( A(G) \) is called the Artin exponent of \( G \). In his paper, he studied \( A(G) \) extensively for many groups. He has shown that \( A(G) \) can be evaluated by knowing the Artin characters of \( G \) and that \( A(G) \) is equal to one if and only if \( G \) is cyclic.

Now, This thesis concentrates on the constructing of the character table of the irreducible rational representation and Artin’s characters induced from all cyclic subgroups of \( SL(2,2^k) \) where \( k \) natural number, \( k>1 \). We have found in this work that: \( a(SL(2,2^k)) = 2^{k-1} \).

2- Representation Theory

**Definition (2.2), [1, 9]**

The set of all \( n \times n \) non-singular matrices over the field \( \mathbb{C} \) of complex number under the operation of matrix multiplication is called the general linear group of dimension \( n \) over the field \( \mathbb{C} \) denoted by \( GL(n, \mathbb{C}) \).

**Definition (2.3), [11]**

Let \( R:G \rightarrow GL(n, \mathbb{C}) \) a representation of \( G \). The complex valued function \( \chi:G \rightarrow \mathbb{C} \) defined by \( \chi(x) = \text{Trace}(R(x)) \) is called the character of \( x \) afforded by the representation \( R \).

**Definition (3.1), [8]**

Let \( R:G \rightarrow GL(n, \mathbb{C}) \) a representation of \( G \). The complex valued function \( \chi:G \rightarrow \mathbb{C} \) defined by \( \chi(x) = \text{Trace}(R(x)) \) is called the character of \( x \) afforded by the representation \( R \).

**Definition (3.2), [5, 7]**

Let \( x, y \) be two elements of a group \( G \), then we said that \( x, y \) be conjugate if \( \exists \ g \in G \) such that \( g^{-1} x g = y \).

**Definition (3.3), [10, 16]**

Let \( G \) be a finite group, \( F:G \rightarrow \mathbb{C} \) which is constant on the conjugate classes of \( G \) is called class function.

4. Induced characters [5]:

**Definition (4.1), [8]**

Let \( H \leq G \) and \( X:H \rightarrow \mathbb{C} \) be any class function. Then the induced character

\[
\text{Ind}_H^G X(g) = \sum_{h \in G} X(h^{-1} g h) h \in G
\]

where \( X(g) = 0 \) if \( g \not\in H \).

**Definition (4.2), [10]**

The least integer \( A(G) \) such that \( A(G) \Phi \) is an integral linear combination of the induced principal characters of the cyclic subgroup of \( G \), for all rational valued characters \( \Phi \) of \( G \), \( A(G) \) is called the Artin exponent of \( G \).
Definition (4.3), [4]:

The integer linear combination of arbitrary character induced from the cyclic subgroups of G, a(G) is determined as the least integer such that a(G) X is an integral linear combination of characters induced from cyclic subgroups of G, for all character X of G.

Notation:

The character induced from the characters of its cyclic subgroups of G is called Artin's exponent. Artin exponent a(G) of finite groups:

Definition (5.1), [6]:

If <t> is a cyclic subgroup of G we define n(t)=n(<t>) to be the number of subgroup <s> of <t> such that \(N_G<s>/C_G<s>\) is non trivial.

Theorem (5.2): (Main Theorem)

Let G be a non cyclic group of order P^n. Let k≥0. The following conditions are necessary and sufficient that a(G)≤P^k.

1) For each element \(\chi\) of order P in G, \(a(N_G<\chi>/C_G<\chi>)≤P^k\).

2) For each element \(\chi\) of order P in G, there exists a cyclic subgroup <t> containing <\chi> such that \(n(t)≥m-k-1\), where \(|N_G<\chi>|=P^m\).

Proof:

See [6].

Definition (5.3), [6]:

Let G be a finite group, the integral linear combination of arbitrary characters induced from the cyclic subgroups of G is called Artin's exponent of G and denoted by a(G).

Definition (5.4), [6]:

Let G be a finite group, the least integer such that a(G)X is an integral linear combination of characters induced from cyclic subgroup of G, for all characters X of G.

6. The Special Linear Group:

Definition (6.1), [1, 5, 9]:

The general linear group over the field F is the group of n×n invertible (non singular) matrices, together with the operation of ordinary matrix multiplication. These form a group, because the product of two invertible matrices is again invertible, and the inverse of an invertible matrix is invertible.

Definition (6.2), [2]:

The general linear group over the field F is the group of n×n invertible matrices denoted by GL(n,F). the determination of these matrices is a homomorphism from GL(n,F) into F*. Thus SL(n,F) is the subgroup of GL(n,F) which contains all matrices of determinate one and it is called special linear group.

Theorem (6.3):

Let G=SL(2,2^k) has exactly \((2^k+1)\) conjugacy classes \(C_g\) for \(g\) \in \(G\) the table (1).

Proof:

See [5].

7. The Artin Exponent a(G) of SL(2,2^k):

Theorem (7.1):

Let G= SL(2,2^k), k=natural, k>1. Then a(G)=2^{k-1} and the table of characters induced from the characters of all its cyclic subgroups see table (2).
Thus $a = (SL(2,2))$ has cyclic subgroups see table (4):-

Example (7.2): If $k = 2$ then $G = SL(2,2^2)$ has exactly $(2^2 + 1)$ conjugacy classes $C_g$ for $g \in G$ see table (3).

Proof:

$| SL(2,2^k)| \leq 2^k (2^{2k}-1)$ (by lemma (3.2.6))

From theorem (3.4.5.), $G = SL(2,2^k)$ has exactly $(2^2 + 1)$ conjugacy classes $C_g$ for $g \in G$ see table (3).

By the definition of inducing we obtained the induced characters $\Phi_1, \Phi_2, \Phi_3$ and $\Phi_4$ of $SL(2,2^k)$ from the characters of all cyclic subgroups see table (4):-

Then we have the following table (5):

- By multiply $\Phi_4$ by $-1$ we get:
  $$-l = (2^k - 1)$$
- By multiply $\Phi_3$ by $-1$ we get:
  $$-m = (2^{2k} - 1)$$
- By multiply $\Phi_2$ by $-1$ we get:
  $$-n = (2^{3k} - 1)$$
- By multiply $\Phi_1$ by $(1/2^k)$ we get:
  $$-1/2^k \Phi_2 = (2^{2k} - 1)/2^{2k} = - (2^{2k} - 1)$$

And then adding the result to $\Phi_1 = 2^k$

$$(2^{2k} - 1)$$

$$2^k (2^{2k} - 1)$$

The conjugacy classes of $SL(2,2^2)$ is $2^k + 1 = 5$, for $g \in G$.

$$1 \leq l \leq 1$$

$$1 \leq m \leq 2^2$$

Then $f, f' = 1$.

Example (7.3): If $k = 3$ then $G = SL(2,2^3)$ has exactly $(2^3 + 1)$ conjugacy classes.

Order of $a$ is 7, order of $b$ is $9$, the divisors of 9 is 1, 3, 9, $f = 1, 3$ see table (8) and table(9).
