#### Abstract

The set of all $\mathrm{n} \times \mathrm{n}$ non singular matrices over the field F form a group under the operation of matrix multiplication, This group is called the general linear group of dimension $n$ over the field F , denoted by $\mathrm{GL}(\mathrm{n}, \mathrm{F})$. The subgroup from this group is called the special linear group denoted by $\operatorname{SL}(\mathrm{n}, \mathrm{F})$. We take $\mathrm{n}=2$ and $\mathrm{F}=2^{\mathrm{k}}$ where k natural, $\mathrm{k}>1$. Thus we have $\operatorname{SL}\left(2,2^{\mathrm{k}}\right)$. Our work in this thesis is to find the Artin's exponent from the cyclic subgroups of these groups and the character table of it's. Then we have that: a $\operatorname{SL}\left(2,2^{k}\right)$ is equal to $2^{k-1}$.

Keywords: Linear Group, Special Group, Exponent.

## 1-Introduction

In this work our focus will lie on the representation and character theory of finite groups. $\mathrm{R}(\mathrm{G})$ is the group of all rational valued characters of G under point - wise addition, and $\mathrm{T}(\mathrm{G})$ is the group generated by the induced characters from the principal characters of certain subgroups of $G$ satisfying the
three conditions of Solomon theorem .Solomon theorem states that the factor group $\mathrm{R}(\mathrm{G}) / \mathrm{T}(\mathrm{G})$ has a finite exponent dividing $|\mathrm{G}|$. E-Artin in (1927) proved that every rationally valued character of $G$ is rational sum of representation character of G , or in other words, the exponent of $\mathrm{R}(\mathrm{G}) / \mathrm{T}(\mathrm{G})$ is finite.

[^0]In (1968) Lam proved a sharp form of Artin's theorem, he determined that the least positive integer $A(G)$ such that $A(G) x$ is an integral linear combination of the induced principal characters of cyclic subgroups, for any rational valued character $\chi$ of $\mathrm{G}, \mathrm{A}(\mathrm{G})$ is called the Artin exponent of G . In his paper, he studied $\mathrm{A}(\mathrm{G})$ extensively for many groups. He has shown that $\mathrm{A}(\mathrm{G})$ can be evaluated by knowing the Artin characters of $G$ and that $A(G)$ is equal to one if and only if $G$ is cyclic.

Now, This thesis concentrates on the constructing of the character table of the irreducible rational representation and Artin's characters induced from all cyclic subgroups of $\operatorname{SL}\left(2,2^{k}\right)$ where k natural number, $\mathrm{k}>1$. We have found in this work that: $\mathrm{a}\left(\mathrm{SL}\left(2,2^{\mathrm{k}}\right)\right)=2^{\mathrm{k}-1}$.

## 2- Representation Theory <br> Definition (2.2), [1, 9]

The set of all $\mathrm{n} \times \mathrm{n}$ non- singular matrices over the field $\$$ of complex number under the operation of matrix multiplication is called the general linear group of dimension $\mathbf{n}$ over the field $\Phi$ denoted by GL(n, $\downarrow$ ).

## Definition (2.3), [11]

Let $\mathrm{R}: \mathrm{G} \rightarrow \mathrm{GL}(\mathrm{n}, \mathrm{¢})$ be a matrix representation of $G$, then $R$ is said to be reducible if for any $x \in G, R(x)$ is equivalent to a matrix of the form

$$
\mathrm{M}^{-1} \mathrm{R}(\mathrm{x}) \mathrm{M}=\left(\begin{array}{ll}
R_{1}(x) & E(x) \\
0 & R_{2}(x)
\end{array}\right), \forall x \in G
$$

where $R_{1}(x), R_{2}(x)$ are two representations of $G$. $\mathrm{R}_{1}(\mathrm{x}), \mathrm{R}_{2}(\mathrm{x})$, and $\mathrm{E}(\mathrm{x})$ are matrices over $\phi$ of dimensions $\mathrm{r} \times \mathrm{r}$,
${ }^{\mathrm{s} \times \mathrm{s}}$ and
$(\mathrm{n}-\mathrm{r})(\mathrm{n}-\mathrm{s})$ respectively, such that $0<\mathrm{r}$
$<\mathrm{n}$ and $\mathrm{r}+\mathrm{s}=\mathrm{n}$ Otherwise then the
representation is called irreducible
Remark (2.4):
Any one dimensional
representation is irreducible.

## 3. Character Theory

Definition (3.1), [8]:
Let $\quad \mathrm{R}: \mathrm{G} \rightarrow \mathrm{GL}(\mathrm{n}, \mathrm{\phi}) \quad \mathrm{a}$ representation of $G$. the complex valued function $\mathrm{X}: \mathrm{G} \rightarrow \mathrm{G}$ defined by $\chi(\mathrm{x})=\operatorname{Trace}(\mathrm{R}(\mathrm{x}))$ is called the character of $\mathbf{x}$ afforded by the representation

## Definition (3.2), [5,7] :

Let $\mathrm{x}, \mathrm{y}$ be two elements of a group G , then we said that $\mathrm{x}, \mathrm{y}$ be conjugate if $\exists \mathrm{g} \in \mathrm{G}$ such that $\mathrm{g}^{-1} \mathrm{xg}$

$$
=y
$$

## Definition (3.3), [10,16]:

Let G be a finite group, $\mathrm{F}: \mathrm{G} \rightarrow \mathrm{\Phi}$ which is constant on the conjugate classes of G is called class function .

## 4. Induced characters [5]:

Definition (4.1), [8]:
Let $\mathrm{H} \leq \mathrm{G}$ and $\mathrm{X}: \mathrm{H} \rightarrow \mathrm{C}$ is a character (or any class function). Then the induced character

$$
\operatorname{Ind}_{H}^{G} \quad X(g) \sum_{h \in G} X\left(h g h^{-1}\right)=
$$

(1/|H|)
where $\mathrm{X}(\mathrm{g})=0$ if $\mathrm{g} \not \mathrm{H}$
Definition (4.2), [10]:
The least integer $A(G)$ such that $\mathrm{A}(\mathrm{G}) \Phi$ is an integral linear combination of the induced principal characters of the cyclic subgroup of G, for all rational valued characters $\Phi$ of $G, A(G)$ is called the Artin exponent of G.

## Definition (4.3), [4]:

The integer linear combination of arbitrary character induced from the cyclic subgroups of $G, a(G)$ is determined as the least integer such that $a(G) X$ is an integral linear combination of characters induced from cyclic subgroups of $G$, for all character X of G .

## Notation:

The character induced from the characters of its cyclic subgroups of $G$ is called Artins exponent
5. Artin exponent $\mathbf{a}(\mathbf{G})$ of finite groups:
Definition (5.1), [6]:
If $\langle t\rangle$ is a cyclic subgroup of $G$ we define $n(t)=n(\langle t\rangle)$ to be the number of subgroup <s>of <t> such that $\left.\mathrm{N}_{\mathrm{G}}<\mathrm{s}>/ \mathrm{C}_{\mathrm{G}}<\mathrm{s}\right\rangle$ is non trivial.

## Theorem (5.2): (Main Theorem)

Let $G$ be a non cyclic group of order $\mathrm{P}^{\mathrm{n}}$. Let $\mathrm{k} \geq 0$. The following conditions are necessary and sufficient that $a(G) \leq \mathrm{P}^{\mathrm{k}}$.

1) For each element $\chi$ of order P in
$\mathrm{G}, \mathrm{a}\left(\mathrm{N}_{\mathrm{G}}(\langle\chi>) /<\chi>) \leq \mathrm{P}^{\mathrm{k}}\right.$
2) For each element $\chi$ of order P in G, there exists
a cyclic subgroup <t>
containing $\langle\chi\rangle$ such that
$\mathrm{n}(\mathrm{t}) \geq \mathrm{m}-\mathrm{k}-1$, where
$\left|\mathrm{N}_{\mathrm{G}}<\chi>\right|=\mathrm{P}^{\mathrm{m}}$.

## Proof:

See [6].
Definition (5.3), [6]:
Let $G$ be a finite group, the integral linear combination of arbitrary characters induced from the cyclic subgroups of $G$ is called Artin's exponent of $G$ and denoted by a(G).

## Definition (5.4), [6]:

Let $G$ be a finite group, the least integer such that $a(G) X$ is an integral linear combination of characters induced from cyclic subgroup of $G$, for all characters $X$ of G.
6. The Special Linear Group:

Definition (6.1), [1, 5, 9,]:
The general linear group of degree $\mathbf{n}$ in the set of $n \times n$ invertible (non singular) matrices, together with the operation of ordinary matrix multiplication. These form a group, because the product of two invertible matrices is again invertible, and the inverse of an invertible matrix is invertible.
Definition (6.2), [2] :
The general linear group over the field $\mathbf{F}$ is the group of $\mathrm{n} \times \mathrm{n}$ invertible matrices denoted by $\mathrm{GL}(\mathrm{n}, \mathrm{F})$. the determination of these matrices is a homomorphism from $\mathrm{GL}(\mathrm{n}, \mathrm{F})$ into $\mathrm{F}^{*}$. Thus $\mathrm{SL}(\mathrm{n}, \mathrm{F})$ is the subgroup of $G L(n, F)$ which contains all matrices of determinate one and it is called special linear group .

## Theorem (6.3):

Let $\mathrm{G}=\mathrm{SL}\left(2,2^{\mathrm{k}}\right)$ has exactly $\left(2^{\mathrm{k}}+1\right)$ conjugacy classes $C_{g}$ for $g \in$ Gas the table (1).

## Proof:

See [5].
7.The Artin Exponent $\mathbf{a}(\mathbf{G})$ of SL( $2,2^{k}$ ):
Theorem (7.1):
Let $\mathrm{G}=\mathrm{SL}\left(2,2^{\mathrm{k}}\right), \mathrm{k}=$ natural, $\mathrm{k}>1$. Then $\mathrm{a}(\mathrm{G})=2^{\mathrm{k}-1}$ and the table of characters induced from the characters of all its cyclic subgroups see table (2).

## Proof:

$\mid$ SL $\left(2,2^{\mathrm{k}}\right) \mid=2^{\mathrm{k}}\left(2^{2 \mathrm{k}}-1\right)$ (by lemma (3.2.6))

From theorem (3.4.5.), $G=\operatorname{SL}\left(2,2^{\mathrm{k}}\right)$ has exactly $\left(2^{\mathrm{k}}+1\right)$ conjugacy classes $C_{g}$ for $g \in G$ see table (3).
where:-
$1 \leq \ell \leq\left(2^{\mathrm{k}}-2\right) / 2$ and $1 \leq \mathrm{m} \leq$ $2^{\mathrm{k}} / 2$

By the definition of inducing we obtained the induced characters $\Phi_{1}, \Phi_{2}, \Phi_{3}$ and $\Phi_{4}$ of $\operatorname{SL}\left(2,2^{\mathrm{k}}\right)$ from the characters of all cyclic subgroups see table(4):-
Then we have the following table see table(5) :
By multiply $\Phi_{4}$ by -1 we get:

$$
-\ell\left(2^{\mathrm{k}}\left(2^{\mathrm{k}}+1\right)\right)
$$

By multiply $\Phi_{3}$ by -1 we get:

$$
-\mathrm{m}\left(2^{\mathrm{k}}\left(2^{\mathrm{k}}-1\right)\right)
$$

By multiply $\Phi_{2}$ by - $\left(1 / 2^{\mathrm{k}-1}\right)$ we get:
$-1 / 2^{\mathrm{k}-1} \Phi_{2}=-\left(2^{\mathrm{k}-1}\left(2^{2 \mathrm{k}}-1\right) / 2^{\mathrm{k}-1}\right)=-\left(2^{2 \mathrm{k}}-\right.$ 1)

And then adding the result to $\Phi 1=2^{k}$
$\left(2^{2 k}-1\right)$ we get:
$-\mathrm{m} 2^{\mathrm{k}}\left(2^{\mathrm{k}}-1\right)-\ell 2^{\mathrm{k}}\left(2^{\mathrm{k}}+1\right)-\left(2^{2 \mathrm{k}}-1\right)$
$+2^{\mathrm{k}}\left(2^{2 \mathrm{k}}-1\right)$

$$
=-2^{\mathrm{k}} / 2\left(2^{\mathrm{k}}\left(2^{\mathrm{k}}-1\right)\right)-\left(\left(2^{\mathrm{k}}-2\right) / 2\right) 2^{\mathrm{k}}
$$

$$
\left(2^{\mathrm{k}}+1\right)-2^{2 \mathrm{k}}+1+2^{3 \mathrm{k}}-2^{\mathrm{k}}
$$

$$
=-2^{2 \mathrm{k}-1}\left(2^{\mathrm{k}}-1\right)-2^{2 \mathrm{k}-1}\left(2^{\mathrm{k}}+1\right)+2^{\mathrm{k}}\left(2^{\mathrm{k}}+1\right)
$$

$$
+2^{3 \mathrm{k}}-2^{2 \mathrm{k}}-2^{\mathrm{k}}+1
$$

$$
=-2^{3 \mathrm{k}-1}+2^{2 \mathrm{k}-1}-2^{3 \mathrm{k}-1}-2^{2 \mathrm{k}-}
$$

$$
{ }^{1}+2^{2 \mathrm{k}}+2^{\mathrm{k}}+2^{3 \mathrm{k}}-2^{2 \mathrm{k}}-2^{1 \mathrm{k}}+1
$$

$$
=2^{3 \mathrm{k}}\left(-\frac{1}{2}-\frac{1}{2}+1\right)+1=1
$$

Thus $\mathrm{a}\left(\mathrm{SL}\left(2,2^{\mathrm{k}}\right)\right)=2^{\mathrm{k}-1}$.

## Example (7.2):

$$
\text { If } \mathrm{k}=2 \Rightarrow \mathrm{G}=\mathrm{SL}\left(2,2^{2}\right) \text { :- }
$$

$\left|\operatorname{SL}\left(2,2^{2}\right)\right|=2^{\mathrm{k}}\left(2^{2 \mathrm{k}}-1\right)=2^{2}\left(2^{4}-1\right)=60$
The conjugacy classes of $\operatorname{SL}\left(2,2^{2}\right)$ is
$2^{\mathrm{k}}+1=2^{2}+1=5$, for $\mathrm{g} \in \mathrm{G}$
$1, \mathrm{c}, \mathrm{a}^{\ell}, \mathrm{b}^{\mathrm{m}}$ where $1 \leq \ell \leq\left(2^{\mathrm{k}}-2\right) / 2 \Rightarrow$

$$
\begin{aligned}
& 1 \leq \ell \leq 1 . \\
& \quad 1 \leq \mathrm{m} \leq 2^{\mathrm{k}} / 2 \Rightarrow 1 \leq \mathrm{m} \leq 2 . \\
& \mathrm{I}=1,\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right), \mathrm{c}=\left(\begin{array}{ll}
1 & 0 \\
1 & 1
\end{array}\right), \\
& \mathrm{a}=\left(\begin{array}{cc}
v^{1} & 0 \\
0 & v^{-1}
\end{array}\right) \\
& |\langle\mathrm{b}\rangle|=\left|\mathrm{F}^{*}\right|=2^{\mathrm{k}}-1
\end{aligned}
$$

where the order of a is $2^{k}-1=2^{2}-1=3$.
Then $\mathrm{e}, \mathrm{e}^{\prime} \leq 3 / 2 \Rightarrow \mathrm{e}=\mathrm{e}^{\prime}=1$
Also the order of $b$ is $2^{\mathrm{k}}+1=2^{2}+1=5$.

Then $\mathrm{f}, \mathrm{f}^{\prime} \leq 5 / 2 \Rightarrow \mathrm{f}=\mathrm{f}^{\prime}=1$.
See table (6) and table (7)
Example (7.3):
If $\mathrm{k}=3 \Rightarrow \mathrm{G}=\mathrm{SL}\left(2,2^{3}\right)$ :-
The order of SL $\left(2,2^{3}\right)=$

$$
2^{\mathrm{k}}\left(2^{2 \mathrm{k}}-1\right)=2^{3}\left(2^{6}-\right.
$$

1) $=8 * 63=504$

Have exactly $+1=2^{3}+1=9$ conjugacy classes.
Where $1 \leq \ell \leq 2^{3}-2 / 2 \Rightarrow 1 \leq \ell \leq 3$

$$
\begin{aligned}
& 1 \leq \mathrm{m} \leq 2^{3} / 2 \quad \Rightarrow 1 \leq \mathrm{m} \leq 4 \\
& \Rightarrow 1, \mathrm{c}, \mathrm{a}^{1}, \mathrm{a}^{2}, \mathrm{a}^{3}, \mathrm{~b}^{1}, \mathrm{~b}^{2}, \mathrm{~b}^{3}, \mathrm{~b}^{4}
\end{aligned}
$$

Order of a is $7 \Rightarrow \ell=1$
Order of $b$ is 9 , the divisors of 9 is 1 ,
$3 \Rightarrow f=1,3$ see table (8) and table(9).
